Abstract

Introduction: Electrocution deaths are not uncommon and most of the cases are accidental in nature. The study has been carried out to find out the incidence of electrocution deaths in Puducherry. Only few studies were done on electrocution deaths in Puducherry.

Objectives: To analyze the frequency, profile and pattern of injuries among electrocution fatalities in Puducherry.

Materials and Method: The study was carried out by retrospectively collecting the 2-years data of all the medicolegal autopsy cases of electrocution related deaths brought to the Mortuary of Indira Gandhi Medical College & Research Institute, Puducherry from January 2015 to December 2016. The data thus collected were recorded in a proforma and analyzed.

Results and Observations: Electrocution deaths accounted for 0.9% (23 cases) of all the medicolegal autopsies (n=2607) conducted in our autopsy center during the study period. The highest number was observed in the age group of 41-50 years (26.1%). Male outnumbered the female with a male female ratio of 2.83:1. Most of the victims are labourers (56.6%) followed by housewife (17.4%), electrician and businessman (8.7% each respectively), official and student accounting for only 4.3% (Fig. 2). All the electrocution deaths were accidental in nature, suicidal and homicidal cases were not observed in the present study.

Conclusions: The number of electrocution deaths within the present study period are comparatively lower than other studies done in India. Proper maintenance of electrical wires and using safety measures by spreading public awareness would go a long way to bring down the fatality of electrical injuries.

Keywords: Electrocution, Accidental deaths, Electrical current, Injury.

Introduction

Any deaths occurring due to electrical shock to the body is called electrocution. The advent of electricity was taken as a boon to the civilization but use of electricity in domestic households has continued to show an increase in fatality either due to lack of public awareness or utter carelessness on the part of the general public. In today's human life electric current plays a very important role in their domestic and occupational places. Electric current can cause damage to the human body and the exact amount of damage is dependent on the type of electric current, the strength of electric current and mostly on the duration of exposure of the electric current. In developed countries, even with the significant improvement in safety of the product and proper implementation of the rules and regulations there is considerable mortality and morbidity due to electrical injuries.⁽¹⁾ Deaths due to electrocution is emerging into a public health problem especially in the low income countries because of lack of awareness and poor safety issues.⁽²⁾ Indian national data on accidental deaths and suicides for calendar year 2010 & 2011 has reported 9059 & 8945 electrocution deaths respectively, with a share of 2.4% of total accidental deaths.⁽³⁾ Electrocution deaths are almost always accidental and few cases are reported in the forensic work to be suicidal or homicidal in nature in India and abroad.⁽⁴⁻¹¹⁾ Puducherry has reported the highest rate of accidental deaths as compared to the national average. This study was designed to know the frequency, victim's profile, pattern of electrical injuries & manner of death among the study population.

Materials and Method

The study was carried out retrospectively collecting the 2-years data of all the medicolegal autopsy cases of electrocution related deaths brought to the Mortuary of Indira Gandhi Medical College & Research Institute, Puducherry from January 2015 to December 2016. The data thus collected from the history of the cases, from the Police Papers and the medicolegal postmortem examination were recorded in a proforma and analyzed.

Results and Observations

Out of the 2607 medicolegal autopsies analyzed in the present study, electrocution deaths accounted for 0.9% of the total cases. The year-wise incidence of electrocution deaths in the present study is given in Fig. 1. The highest number of electrocution deaths was found in the year 2015.

Fig. 1: Incidence of electrocution death cases

Laborers accounted for the highest number of persons (56.6%) fatally electrocuted in our study followed by housewife (17.4%), electrician (8.7%) and businessman

(8.7%). Electricians and student accounted for 4.3% respectively (Fig. 2).

Fig. 2: Occupation of persons electrocuted

Most of the victims of electrocution were found dead in the place of occurrence (Fig. 3). In 21.73% of the cases the victims were declared dead at the hospital.

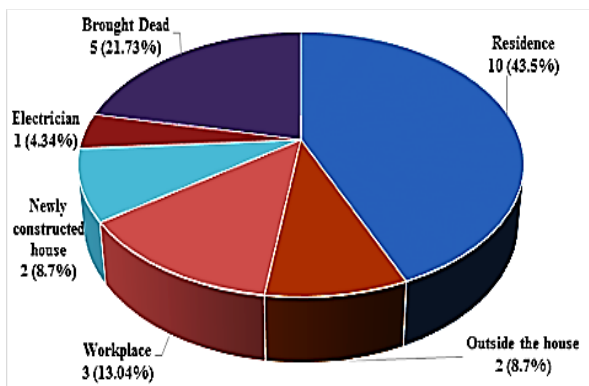

Fig. 3: Place of occurrence of electrocution

In the present series, the electrocution deaths mostly occurred during the daytime accounting for 65.22% of the cases as shown in Fig. 4.

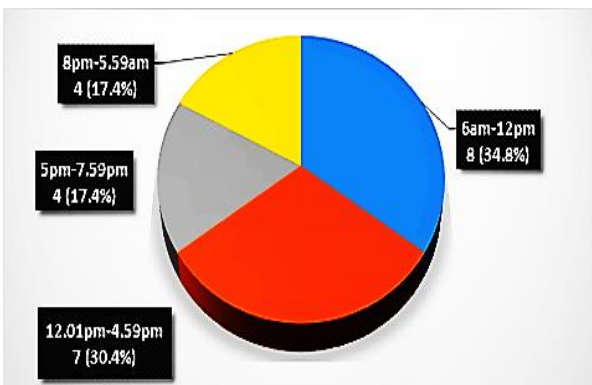

Fig. 4: Time of occurrence of electrocution

The highest number of electrocution deaths was observed during the month of August with 6 cases

(26.1%) and September with 4 cases (17.4%) as shown in Fig. 5.

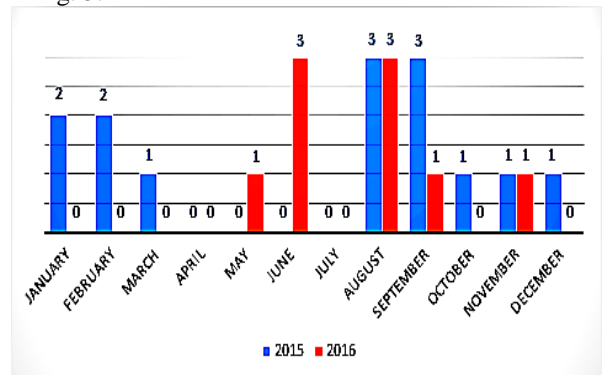

Fig. 5: Month-wise distribution of electrocution cases

Home appliances constituted the most common causative agent (47.8%) followed by high tension wire (34.8%) as shown in Fig. 6.

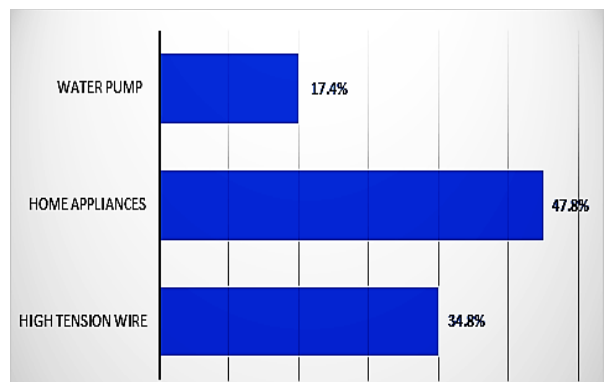

Fig. 6: Causative Agent

There was male preponderance with a male female ratio of 2.83:1. The highest number of electrocution deaths was observed in the age group of 41-50 years (26.1%) followed by the age group of 21-30 years and

31-40 years accounting for 17.4% each respectively (Table 1).

Table 1: Age and Sex distribution of electrocution deaths

Age (Yrs)	Male	%	Female	%	Total	%
0 -10	0	0	0	0	0	0
11-20	2	11.8	0	0	2	8.7
21-30	4	23.5	0	0	4	17.4
31-40	4	23.5	0	0	4	17.4
41-50	4	23.5	2	33.3	6	26.1
51-60	1	5.9	2	33.3	3	13
61-70	2	11.8	1	16.7	3	13
71-80	0	0	0	0	0	0
above 80	0	0	1	16.7	1	4.4
Total	17	100	6	100	23	100

Distribution of entry and exit with site of lesion: In the present study entry wound of electrical injuries along with the corresponding exit were observed in 73.91% of the cases. No entry or exit were observed in the present series (Table 2). The most frequently involved site of entry was observed in the upper extremity (69.56%) followed by the chest and abdomen (13.04%). The exit wounds were mostly observed in the lower extremity (56.52%) and there were no exit wounds in 30.43% of the cases.

Table 2: Distribution of entry and exit with site of lesion

	No of cases	%
Only entry wound	6	26.09
Entry and exit	17	73.91
No entry and exit	0	0
Total	23	100
Site of lesion (entry wound)		
Upper extremity	16	69.56
Lower extremity	2	8.7
Head and neck	2	8.7
Chest and abdomen	3	13.04
No entry	0	0
Total	23	100
Site of lesion (Exit wound)		
Upper extremity	2	8.7
Lower extremity	13	56.52
Head and neck	0	0
Chest and abdomen	1	4.35
No exit	7	30.43
Total	23	100

Discussion

Normally electrocution is simply the result of an accident and it kills many people every year. The major reasons for accidental electrocution deaths could be due to carelessness or it could also be due to ignorance or technical defects. In the present study male constituted 73.9% of the cases which is consistent with findings of

other authors.⁽⁹⁻¹⁴⁾ Male outnumbered the females in our study could be due to the fact that females normally do not associate with repair of electrical appliances as compared to their male counterparts. The incidence of electrocution deaths in our study were 0.9% which is similar to findings of Laupland et al.⁽¹⁴⁾ This findings were significantly lower compared to studies done in India^(8,9,13,15) and abroad⁽¹⁶⁾ where they reported varying incidence of electrocution deaths of 1.98%, 2.2%, 1.93%, 2.56% and 3.3% respectively. The highest number of electrocution deaths were observed in the age group of 41-50 years (26.1%) followed by the age group of 21-30 years (17.4%) and 31-40 years (17.4%). Previous researchers^(11,12,17,18,20) found 21-30 years as the most common age group which is not in agreement with our study. In the present study electrocution deaths in the age group of 51-60 years and 61-70 years were found to be 13% of the total cases respectively. There were no minor victims of electrocution below the age group of 10 years which is consistent with the findings of Pathak et al.⁽¹⁵⁾ Gupta BD et al⁽⁹⁾ found 7.84% of the cases under the age of 10 years. There were 2 cases (8.7%) of electrocution deaths under the age of 20 years (all were males) which is significantly lower than the findings of Kuitic I et al.⁽¹⁰⁾ In our study there was one 81-years old lady who got electrocuted when a coconut tree fell on a high tension wire and she came in contact with the live electric wire. Maximum number of victims (10 cases, 43.5%) died at home which is in agreement with other authors^(9,15) and 5 cases (21.73%) were brought dead. Only 3 cases (13.04%) died at the work place whereas other authors^(10,12,15,18,19) found higher incidence of electrocution deaths in the workplace. Many of the workers are exposed to the electrocution hazards as they often misjudge the existing dangers of live electric wires or the arcing of high-tension power cables dangling nearby. And this could be the reason for the considerable amount of morbidity and mortality seen during their working activities. Kuitic et al⁽¹⁰⁾ found 32% of fatal electrocution among the electricians whereas in our study we found only 4.34% of the cases which is significantly lower than their findings. The electrician

was performing his usual job at the time of being electrocuted. In regards to seasonal variations the incidence of electrocution deaths were significantly higher during the month of August and September which is in agreement with other studies.^(12,15) Majority of the incidences (65.2%) occurred during the daytime which is consistent with the findings of other authors.⁽¹⁵⁾ The majority of cases had both the entry and the exit wound (17 cases, 73.91%) which is consistent with the findings reported by other researchers.⁽¹⁷⁾ There were 26.09% of the cases with only entry wound which is significantly lower than the findings of other authors.⁽¹⁶⁾ In majority of the cases (69.56%) of entry wounds the upper extremity was the most common body part involved and 56.52% of exit wounds were observed in the lower extremity which is consistent with the findings of other researchers.^(8,9,12,15,19) Lower extremity and head & neck accounted for 8.7% of the cases respectively for the entry wound which is significantly lower than the study done by Guntheti et al⁽²⁰⁾ where they found 37.50% of entry wounds in the head and neck. Chest and abdomen was involved in 13.04% of the cases of the entry wound. Low-voltage cases accounted for the majority of the cases of fatal electrocution in our study with 65.2% of the cases which is in contrast to Ragui S et al⁽¹⁷⁾ where the majority of the cases were due to high tension electrocution.

Conclusion

Electrocution deaths were found to be much lower among all the medicolegal deaths in the present study compared to studies done by other authors. Most of the cases are due to accidental touching of live electric wire or accidental fall on live electric wire on the victims. Proper maintenance of electrical wires and using safety measures by spreading public awareness would go a long way to bring down the fatality of electrical injuries.
